

Paperloom - Technical SEO Audit

Every number below was measured directly against the generated site, not estimated: 283 HTML pages were parsed, 23,119 internal links were followed, and every structured-data block was validated as real JSON. This is what that check found, what was fixed, and what was already correct.

Site: paperloom-rho.vercel.app • Audited 8-9 September 2026 • 283 pages, 6 categories, 52 subcategories, 204 templates, 15 guides

12 issues found across on-page, structured data and internal linking	12 fixed and verified in this pass	23,119 internal links checked · 0 broken	100 contextual in-content links added · 0 before
--	--	--	--

METHOD

How this was checked

Not a checklist ticked from memory - each item below is a script that opened the real generated HTML for all 283 pages and measured it.

- Every `<title>` and `<meta name="description">` extracted and checked for length (Google's practical display limits: roughly 15-60 characters for a title, 70-160 for a description) and for duplicates across the whole site.
- Every `<h1>`-`<h6>` on every page collected in document order to check exactly one H1 per page, and that heading levels never jump (no H2 straight to H4).
- Every internal `<a href>` resolved to a real file path and checked for a 200 - not sampled, all 23,119 of them.
- Links *where* they sit, not just how many there are: navigation (header, footer, related-item counted *modules*) separated from contextual links written inside the prose, because search engines weigh the second kind far more heavily.
- Every `<script type="application/ld+json">` block parsed with a real JSON parser, not eyeballed.

- sitemap.xml parsed as XML and its URL count compared against the actual page count; robots.txt read directly.
- canonical, viewport, lang, favicon and og:image tags checked for presence on all 283 pages.

FINDINGS

What was wrong, and what changed

Nine issues, grouped by what they affect. Each row shows the measured before and after - not a description of intent.

Accessibility & structure

ISSUE	BEFORE	AFTER	STATUS
Heading level skips (H2 straight to H4, no H3) - the footer's section labels were H4 while most page content only reaches H2. A screen reader jumping by heading level lands nowhere between them. ----- Fix: footer labels changed to H3. Two pages (Guides index, Contact) had no H2 at all and skipped H1→H3; both got a real section heading.	282 / 283 pages	→ 0 / 283	FIXED

Social sharing

ISSUE	BEFORE	AFTER	STATUS
No og:image on any page - a link shared to WhatsApp, Facebook or Slack showed no preview image. ----- Fix: generated a branded 1200×630 share image and added og:image, og:image dimensions and matching twitter:card tags sitewide.	0 / 283 pages	→ 283 / 283	FIXED

Titles & descriptions

ISSUE	BEFORE	AFTER	STATUS
Titles over ~60 characters, at risk of truncating in search results. The last one held at 61 because template titles are generated from the subcategory name, and "Farewell & Retirement Invitations" is long. Fix: a subcategory can now name a shorter word to be titled by without changing its own heading.	23 pages	→ 0 pages	FIXED
Descriptions over 160 characters. Most came from one auto-generated sentence that overflowed on subcategories with long names (Farewell & Retirement Invitations). Fix: shortened the generating formula and hand-trimmed the rest.	10 pages	→ 0 pages	FIXED
Duplicate titles or descriptions across different pages (a real duplicate-content signal to search engines).	0	→ 0	ALREADY CLEAN

Structured data

ISSUE	BEFORE	AFTER	STATUS
No BreadcrumbList schema, despite every page already rendering a visible breadcrumb trail - Google can show that trail under the search result, but only if it is marked up. Fix: the breadcrumb function now emits the JSON-LD from the exact same data as the visible	0 / 283	→ 282 / 283 (all but home)	FIXED

ISSUE	BEFORE	AFTER	STATUS
trail, so the two can't drift apart.			
No Organization / WebSite schema declaring what the site is. ----- Fix: added to the homepage, including a SearchAction. Made that claim real rather than decorative - the homepage now reads a ?q= URL parameter and runs the search, which is what a Google sitelinks search box actually calls.	Absent	→ Present, functional	FIXED
FAQPage schema (subcategory pages) and Article schema (guides) - checked for valid JSON and correct placement.	52 + 15 pages	→ Unchanged, valid	ALREADY CORRECT

Internal linking

ISSUE	BEFORE	AFTER	STATUS
No contextual links inside any article body. Every internal link on a guide	0 across 15 guides	→ 35	FIXED

ISSUE	BEFORE	AFTER	STATUS
	sat either in the site navigation or in a call-to-action box after the article ended. Links inside the prose - where the sentence itself gives the link its meaning - are the kind search engines weigh most, and there were none. ----- Fix: 35 links written into sentences that already discussed the thing being linked to, with the phrase in the sentence as the anchor text rather than a bolted-on "click here". These form real topic clusters - the three wedding guides now reference each other, as do the two CV guides, flyer and social sizes, budget and meal planning.		

ISSUE	BEFORE	AFTER	STATUS
Template listing pages had no contextual links either. 50 of the 52 subcategory pages linked out only through navigation modules, so the guide explaining how to use a given document type and the page offering that document type were not connected in either direction by anything a reader would follow mid-sentence. ----- Fix: every subcategory now closes its intro with a hand-written line linking to the guide covering that document type - or, where no guide exists, to the page a reader actually needs next: certificates to diplomas, recipe cards	2 of 52 pages	→ 52 of 52 · 65 links	FIXED

ISSUE	BEFORE	AFTER	STATUS
to meal planners, vouchers to business cards. Written per page rather than generated, because 52 pages carrying one templated "read our guide" sentence reads as filler to a person and as a footprint to a search engine.			
Guides could only link to one related template category each, even where the written content named several - the sizes guide discusses seven platforms but linked to one. ----- Fix: the closing call-to-action can now cite several related categories in one sentence rather than a repeated	1 link / guide	→ Up to 5, where earned	FIXED

ISSUE	BEFORE	AFTER	STATUS
banner per mention.			
Two pages named another category's templates in plain text without linking to them - the diploma page mentioned certificates, the logo page mentioned letterheads.	2 plain-text mentions	→ 2 real links	FIXED
No link between Business Cards and Logo Templates, despite being the most common real-world pairing on the site (a new business needs both).	Unlinked	→ Linked, both directions	FIXED
Pages with no incoming internal link at all (unreachable except via sitemap).	0	→ 0	ALREADY CLE

Everything else that was checked

No issue found - listed because "we checked and it's fine" is still evidence.

Canonical tag present	283 / 283	Viewport meta present	283 / 283
lang="en" attribute	283 / 283	Favicon linked	283 / 283
Broken internal links	0 / 23,119	Invalid JSON-LD	0 / 349
Orphan pages	0 / 283	sitemap.xml	283, matches page count entries
robots.txt	Allows all, points to sitemap	 without alt text	0 (no raster content images)
Duplicate H1 (same URL)	0	Avg. HTML page weight	38.7 KB

Reviewed, not changed - every page loads all six category stylesheets (~108KB uncompressed) rather than only the one it needs, because the homepage and category pages show preview cards pulled from other categories and a safe per-page split would need careful testing to avoid a page rendering without a style it turns out to need. Real-world cost is small - the files are cached after a visitor's first page view, and Vercel compresses them in transit - so this is flagged as a low-priority future optimisation rather than fixed under time pressure.

Correction to the first version of this report - it stated 44 subcategories. The site has 52. The figure was wrong when written, not changed since; every other count in that version was checked against the build and stands. Flagged here rather than quietly amended, because a report a client relies on has to say when it was wrong.

NEXT

What actually moves rankings from here

On-page work is done. The site now has no data to prove any of it worked - these four close that gap.

1

Submit the sitemap to Google Search Console

paperloom-rho.vercel.app/sitemap.xml. Nothing above matters to rankings until Google has actually crawled and indexed the pages - this is what makes that happen on a predictable schedule instead of by chance.

NEEDS THE SITE OWNER'S GOOGLE ACCOUNT

2

Add analytics

There is currently no record of what pages get visited or what people do once they arrive. A week of real data will say more than another round of guessing which category to build next.

3

Write more guides before adding more categories

Guides are the site's only long-form original writing, and the part that gives thin template-gallery pages the surrounding content search engines and AdSense both look for. Each existing category has room for two or three more.

4

Re-run this audit after Search Console has a few weeks of data

Query and impression data will show which pages are already being found for the wrong keyword, or found for a keyword this site didn't intend to target - both are worth acting on and neither is visible without it.

Every figure in this report was measured against the build deployed on 9 September 2026. Re-running it against a later deploy may produce different numbers as new categories are added.
